

FAINT BLUE STARS IN THE REGION NEAR THE SOUTH GALACTIC POLE

G. Haro and W. J. Luyten*

I. INTRODUCTION

For a number of years the Observatories of Tonantzintla and Minnesota have been engaged, separately and independently, in a search for and observation of faint blue stars in high galactic latitude. We have now felt that it would be useful to join forces, especially when the opportunity presented itself, in the fall of 1958, to obtain the use of the Palomar 48 inch Schmidt telescope through guest-investigator privileges at the Mount Wilson and Palomar Observatories. Altogether we spent two observing periods, October 13-19 and November 4-11 using the 48 inch Schmidt telescope, and took usable plates for forty-nine regions near the South Galactic Pole. All these plates were taken following the Tonantzintla⁽¹⁾ three-image method with one exposure in the ultra-violet, one in the yellow and one in the blue, using 103aD plates and Scott UGI, Wratten No. 12 and No. 47 filters, respectively. We should like to record our indebtedness to Dr. Rudolph Minkowski for designing the frames and adapting the filters in such a way that they were easily changed, which greatly facilitated the execution of the program.

Our exposures were adjusted in such a way that the faint white star in S. A. 68 (No. 59)⁽²⁾ showed three images, such that the yellow image was about 0.1 brighter than the blue, and the ultra-violet and blue images were practically equal. Since this star has a photographic magnitude of 18.56 and a $B - V$ of +0.14, this would ensure that for the faintest images on our plates the three images would be virtually equal for stars of color index 0.0. This resulted in the following lengths of exposure: 40 minutes for the ultraviolet, 4 minutes for the yellow, and 8 minutes for the blue. Yellow and red stars—which predominate—then show a strong central image flanked by two weaker ones, but the blue stars we are searching for show a weak central image between two much stronger ones; thus these blue stars stand out and are easily discovered. Figure 1 shows a sample field in which some very blue and very red stars are identified to illustrate our procedure.

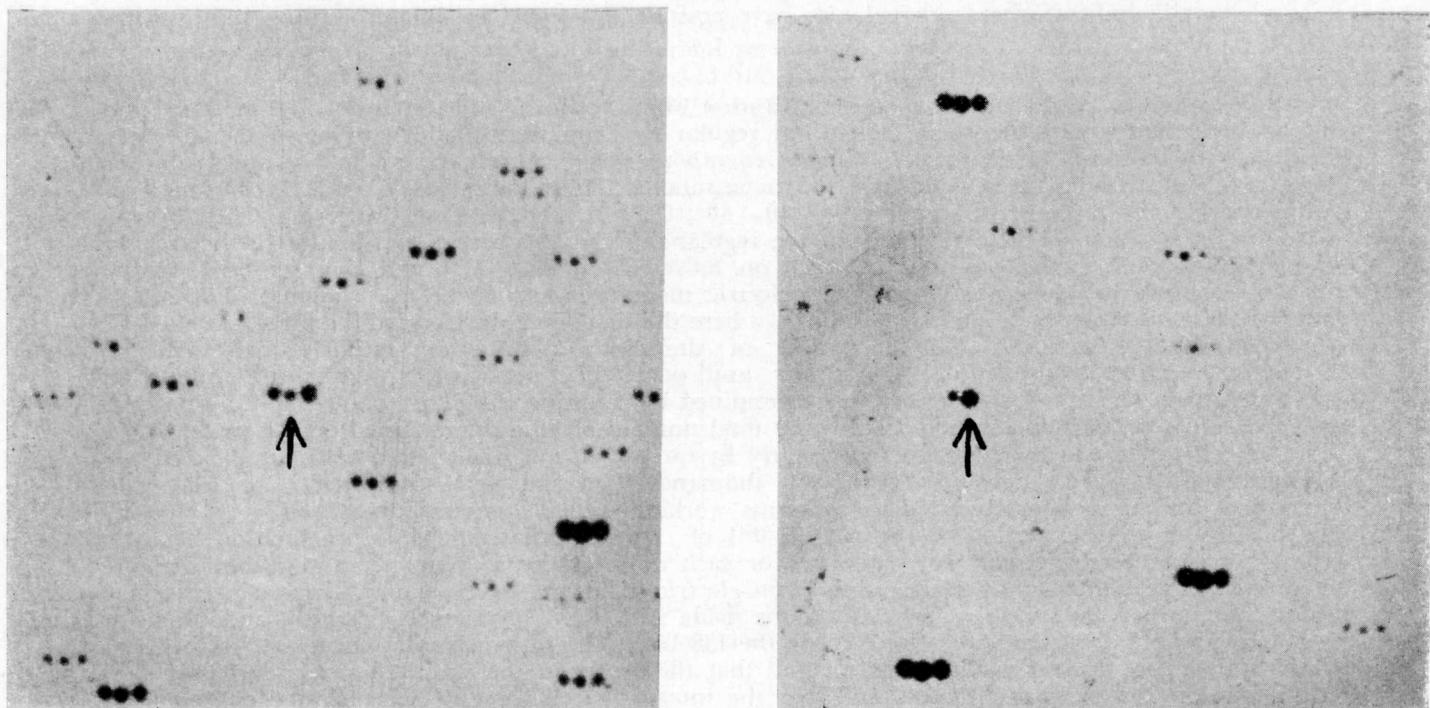

Fig. No. 1.—Three-color photograph of sample fields in which a very blue and a very red star are marked. The three blue-yellow-ultraviolet images are displaced from one another. The blue one is at the left side, the yellow in the middle and the ultraviolet to the right side. The very blue star indicated at the left side of the figure is our blue star PHL 384, the very red star in which only the blue and yellow images appear to the right is probably an N type star at RA 22h41m4 and Dec. +1°30'.

* Astronomical Department, University of Minnesota.

Since our interest lay mainly in the faintest stars that could be reached, the exposure times were adjusted to make their discovery the easiest. We have purposely made no attempt to include the brighter A stars, most of which do not look blue on our plates, partly because our method cannot claim linearity over the entire range from the nineteenth to the seventh magnitude. Even some of the brighter B8 stars from the *Henry Draper Catalogue* were missed in our searches and, in general, we might say that our method of discovering blue stars with color indices not larger than 0.0 works best for the range from about the twelfth to the eighteenth magnitude.

In addition to the bright-star trouble there is a lack of homogeneity among the plates, due to various causes over which the observer has little control, such as the variation in transparency and seeing from night to night, changes in sensitivity over the plate, and perhaps small changes in transmission of the filters in different areas, and finally, most vexing of all, the effect of change in zenith distance. As will be seen in the subsequent tables, the plates taken at declination -30° are mostly very deficient in numbers of blue stars. The best one can say for our method is that faint blue stars are fairly easily discovered with it, but there remains a good deal of subjectivity in it.

Stars that are easily identified —regardless even of the vexing little variations referred to above—are:

- 1) Extremely blue stars, with a $U - B$ of -0.3 to -0.7 in our system.
- 2) Extremely red stars, such as N stars, where the difference between the yellow and blue and between the blue and ultraviolet images often reaches four to six whole magnitudes, and where the ultraviolet image often is completely invisible.
- 3) Ordinary red stars, such as M stars, with color indices of from $+1.2$ to $+2.0$ are fairly easily noticed. In this connection, we should like to remark that we have noticed large numbers of close pairs composed of such red stars having the color index of a class M star.
- 4) Flare stars, T Tauri stars, stars with UV excess, in fact any star which deviates from what, after a little experience, the observer "feels" is the normal relationship between the three images.
- 5) Most galaxies appear with the expected yellow color but we have been struck by the comparatively large number of galaxies that appear definitely blue: possibly this is due to some emission line contribution which passes our filters since photo-electric color measures generally indicate that such galaxies have positive $B - V$ values, but are strong in the ultraviolet.

In order to render subsequent identification of the objects, and determination of their position as convenient as possible, the plates in our regular program were planned to be taken at centers identical with those of the *Palomar-National Geographic Survey*. Originally we had planned for fifty plates evenly distributed in a semi-circle drawn around the South Galactic Pole with a radius of about 45 degrees, but the three plates at centers $21^h40 - 30^\circ$; $0^h00 0^\circ$; and $0^h48 + 6^\circ$ were not taken because of clouds. In addition to these 47 plates in the regular program, we took plates in two further regions for magnitude calibrations, *viz.*, four centered on S. A. 68 ($0^h09 + 15^\circ$) and one centered on M2 ($21^h31 - 1^\circ$) since for these areas good photoelectric magnitude sequences are available. The salient data for these 49 regions are given in Table I, where the first five columns give the plate centers, both equatorially and galactically and the quality of the plate, a subjective estimate expressed only in terms of three qualifications: good, fair and poor. The next column gives the number of stars per square degree, which number was determined by counting the blue (photographic) images in ten small areas on each plate, and finally the total number of blue stars marked on the plate.

Every plate was examined independently by each of us and the total number of different objects originally marked, slightly exceeded ten thousand. The equatorial coordinates for 1950 were determined for all of these by student assistants working under Luyten's supervision at Minnesota. These positions were estimated to the nearest 0^m1 of right ascension and $1'$ of declination by using grids drawn on tracing paper and made up for each of the Palomar zones separately. Photographic magnitudes were estimated by Haro using photo-electric sequences, a few scattered photo-electric magnitudes determined by Iriarte, some calibrations made with the Tonantzintla Schmidt, and by means of a "fly-spanner" for standardization. From the 138 blue stars in overlapping areas and from identifications of previously known blue stars we find that the errors in the positions rarely surpass 0^m2 in right ascension and $2'$ in declination, and that the internal mean error of the magnitudes is $\pm 0^m24$. We may hope, therefore, that the values given in the catalogue are within 0^m5 of the international photographic system as determined photo-electrically.

In addition to the magnitudes, both of us have estimated the color differences in steps by comparing the blue and yellow images on the one hand, and the blue and ultraviolet images on the other hand. Experience has shown that the former color estimates are roughly equal to the $B - V$ values in the Johnson-Morgan system and that the latter roughly equal two-thirds of the $U - B$ values. Again using the 138 stars in the overlapping areas we find that for both of us the internal mean error

of these step estimates is about 0.08 step for both $B - V$ and $U - B$, while for the differences Haro minus Luyten it is about 0.09 step. While again we do not claim great accuracy for our data, this remarkably good agreement between our two sets of data shows that we have something real and that these color estimates constitute the simplest and most easily derived quantitative estimates which can aid us in classifying these stars into several groups.

After comparing our independently derived data and especially after checking all the objects marked on duplicate negatives of the *Palomar-National Geographic Survey*, a large number of objects were rejected. Some of these were galaxies, clearly shown on the Palomar single-image plates, and we can only hope that not too many other galaxies have escaped detection and are still listed among our "blue stars" but this is a calculated risk one has to take. The largest number of objects were rejected from our final catalogue because we did not feel certain that they were blue enough to merit inclusion — many of them may well be early F stars or RR Lyrae variables which ultimately will prove to be of some importance, since obviously a star of photographic magnitude 18.5 and color index +0.1 or +0.2 cannot be, according to the present general astronomical ideas, both a main-sequence star and in the galactic disk. Also excluded were the numerous blue stars immediately surrounding the several globular clusters on our plates, as well as those apparently associated with dwarf galaxies. In this connection, we should like to note the difference between the very blue stars in globular clusters and the very blue and ultraviolet stars in the field — the former never attaining the extreme $U - B$ values of the latter, up to our limiting magnitude.

2. THE CATALOGUE

After all these eliminations 8746 stars remain for which we feel reasonably sure that they are somewhat blue, and data for these are given in the final catalogue. This catalogue is again divided into three parts: Table II, containing the 1569 very definitely blue stars, defined as those for which the sum of our step estimates, *i. e.* $B - V + U - B$ or actually $U - V$, is -0.4 or bluer; a second section, Table III, containing data for 2929 stars for which this same quantity is either -0.3 or -0.2 , and which stars are probably still blue enough to merit individual consideration; and a third section, Table IV, containing the data for the remaining 4248 stars for which $U - V$ has a value of -0.1 or 0.0 . We have retained our individual step estimates only for Table II, since we have felt that for Tables III and IV these would not be sufficiently informative. Nevertheless, a number of interesting stars will be included in these two lists, such as *e. g.* the white dwarf L870-2 (our No. 7450).

From overlapping areas and from repeat-examinations of several plates we can express the hope that for the stars in Tables II and III we are at least eighty percent complete. For the last group, given in Table IV, all sorts of observing troubles and photographic effects, such as slight variations in differential color sensitivity of the plates, threshold exposure effects for faint stars, the possible presence of slight but undetected haze, combined with the obviously much greater subjectivity involved in marking these stars make certain that here our list must be very incomplete. Not only that, but if other observers or even ourselves examined these plates again they, or we, might well again mark 4000 to 5000 stars of this kind but among them there would be no more than 50% of stars in common with our present list of 4248.

In order to obtain some semblance to statistical completeness, we have added data for all stars occurring on our plates and classified as B in the *Henry Draper Catalogue*, even if we did not originally find them. Those stars are 39 in number and have been distributed over Tables III and IV according to our subsequent estimates of their $B - V$ and $U - B$; none that belong in Table II were missed.

The question of accurate identification of these faint objects is a vexing one. After carefully weighing all arguments we have felt that, for the present at least, we should not go to the enormous amount of labor and expense in preparing and printing identification charts. Since the number of astronomers who would wish to observe any of these stars photo-electrically or spectroscopically is still very small, it would seem more efficient to supply identification charts in individual cases. Any astronomers so interested are therefore urged to communicate directly with either of us. We hope, however, that the University of Mexico will shortly be able to publish individual identification charts for all stars included in Table II.

The arrangement of the final catalogue is as follows: The first column gives our serial number for which the designation *PHL* (Palomar-Haro-Luyten) is suggested. At the end of each table some notes have been added, which mainly give identifications and numbers of stars previously found by Chavira⁽³⁾, Cowley⁽⁴⁾, Feige⁽⁵⁾ and Luyten⁽⁶⁾ (independently found by us, but for statistical purposes we have felt it advantageous to use one continuous system of numbering here), and the *BD*, *CoD* or *HD* catalogue numbers. The next two columns give the approximate equatorial coordinates for 1950 and, the next two, the galactic coordinates calculated with the IBM 650 of the University of Mexico and referred to the new galactic pole at $12^{\text{h}}49.0 + 27^{\circ}24$ (1950). The last three columns give the photographic magnitudes and the two color estimates in steps — the latter only for Table II.

In Table V we have made a summary of all the stars contained in Tables II, III and IV, according to their $U - V$ colors and apparent photographic magnitudes. The sudden decrease in num-

bers below 18^m9 merely indicates that the effective plate limit is reached near here, on the average. Below magnitude 18.5 some of the very blue or ultraviolet stars may have been missed because here it is possible that only the ultraviolet image may appear on our plates and not the yellow and blue images.

TABLE V
Summary of all the Stars contained in Tables II, III and IV

Following the main three sections of the catalogue and Table V, a short Table VI gives data for the small number of stars which seem definitely peculiar, such as flare stars or possibly yellow degenerate stars — and which would not fit into any of the first three categories.

TABLE VI

Peculiar Stars

RA. 1950	Dec. 1950	m_{pg}	$B - V$	$U - B$
21 ^h 36 ^m 4	-10°56'	17.1	-0.2	+0.3
41.7	-16 03	17.2	+0.2	-0.3
49.0	-12 54	17.0	-0.1	+0.4
22 17.8	+ 0 54	17.0	+0.1	-0.4
23 17.1	-17 22	18.6	+0.2	-0.3
0 11.0	+ 7 55	16.9	-0.4	+0.8
46.1	-32 16	17.0	-0.2	+0.7
49.4	-19 38	15.7	+0.4	-0.6
1 07.4	-28 50	16.7	-0.2	+0.8
2 45.8	-30 40	18.4	+0.5	-1.0

Shorter, separate Tables VII-X are given, following the main catalogue. These give, in order:

Table VII. Data for 36 pairs of blue stars for which, in addition to the magnitudes and color estimates for both components, the separations and position angles are given in the last two columns. Many of these pairs are probably physical and perhaps a considerable number will turn out to be double white dwarfs.

Table VIII. Data for 71 similar pairs composed of one blue and one yellow or red component. Again some of these are probably physical pairs, especially since in a large number of cases the two components are nearly of the same magnitude.

In both Tables VII and VIII we have restricted inclusion to those pairs with a separation of 20" or less.

Table IX. Data for the five extremely red stars found. The third and fifth in the list might perhaps be M stars, the other three are almost certainly N stars.

Table X. Data for the 24 stars which appear to be variable. Here we note that with the exception of the few possible flare stars, the majority of the blue variables are contained in Table II — the very blue stars. All of these appear very blue at maximum but are not necessarily blue at minimum; moreover, they all seem to belong to the eruptive type, either SS Cygni, Z Camelopardalis or R Coronae Borealis type⁽⁷⁾. Since all these variables were found from a comparison of our single three-image plate with a single Palomar-Survey plate, it is suggested that the actual number of such variables may be very large indeed.

TABLE VII
White or Blue Double Stars

Note to Table X

The stars indicated as flare, with question mark, have been included in this Table mainly because of the very peculiar density relation between the three blue-yellow-ultraviolet images, but there is the possibility that these be some kind of degenerate stars. As to the two other flare stars without question mark, besides the very peculiar color relation observed, variation has been found in some other plates. For one of these stars ($0^{\text{h}}49^{\text{m}}4$, $-19^{\circ}38'$) Dr. G. H. Herbig, of the Lick Observatory, kindly informed us the following: "Two Crossley spectrograms are now available. It is a rather peculiar object; the energy distribution is about like that of a K dwarf, but I can see no lines in the spectrum. It may be a low-luminosity DG star like Wolf 489 or yours and Luyten's LP 658-2".

Finally, as mentioned before, we found a large number of close pairs of red stars. For one of these, LP770-1 at $2:23:36 - 20:18.1$ (1950), relative motion was indicated and from measurement we find that the northern component has a proper motion of $0.^{\text{s}}27$ in about 90° . This, therefore, is an optical pair but it would seem as if a large percentage of the others should be physical pairs; we intend to follow this up by measuring as many proper motions as possible.

The numbers so corrected are shown in the fourth column. The plots of these uncorrected and corrected ratios are shown in Figures 2 and 3. Over the range from -50° to -70° which the data

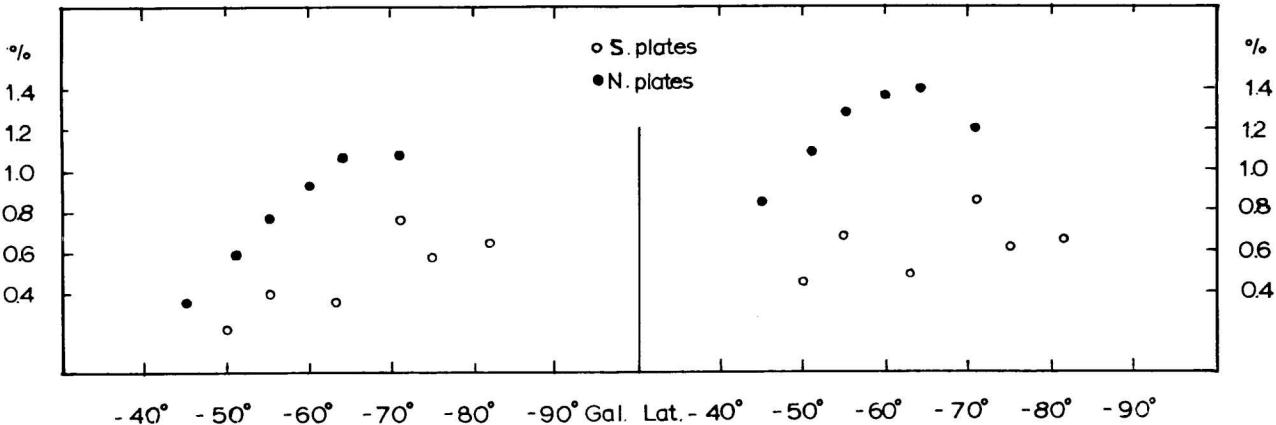

Fig. No. 2.—Plot of the uncorrected ratios of all blue stars/total number of stars expressed in % against the average galactic latitude of each group of plates.

Fig. No. 3.—Similar plot as in Fig. No. 2, but using the corrected ratios.

from both sets of plates have in common, we see an increase in the uncorrected percentages from 0.6 to 1.1 for the northern plates and from 0.3 to 0.55 for the southern plates where, through the declination-extinction effect, the numbers of blue stars are almost exactly half those for the northern plates. The overall averages are 242 blue stars per northern plate and 123 per southern plate. However, the corrected data show virtually no increase at all for the southern plates and, if only the corresponding part of the curve (-50° to -70°) is observed for the northern plates, a very slight but none too well established increase here.

If similar data are obtained for the very blue stars from Table II only we obtain the numbers in columns 5 and 6, the former giving the numbers of very blue stars as ratios to the total numbers, the latter giving these data similarly corrected for the galactic latitude decrease in the total numbers of stars. These data are plotted in figures 4 and 5 and it is seen that the increase in the

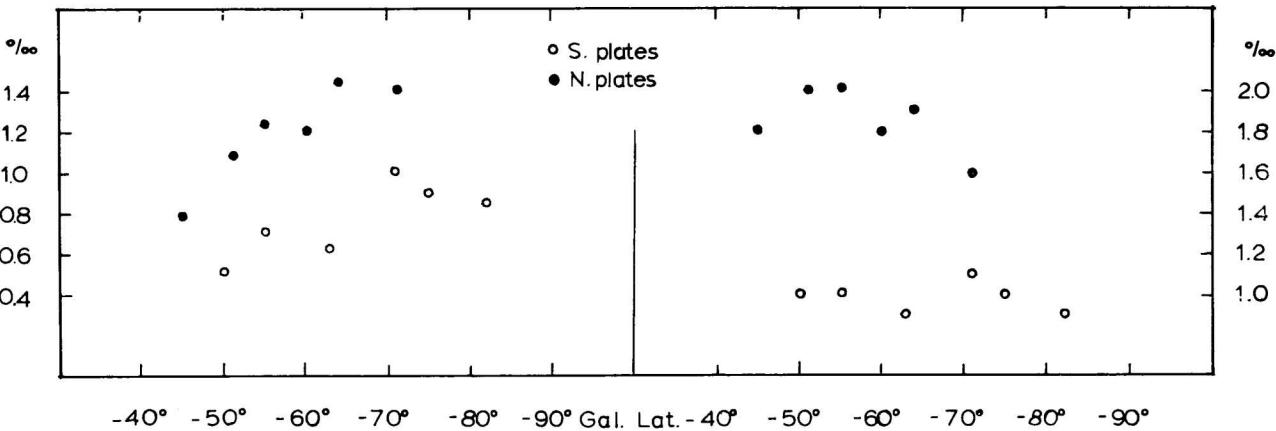

Fig. No. 4.—Plot of uncorrected ratios for very blue stars only, $U-V \leq -0.4$ /total number of stars expressed in % against the average galactic latitude of each group of plates.

Fig. No. 5.—Similar plot as in Fig. No. 4, but using the corrected ratios.

former case is less than that for figure 2, while figure 5 actually suggests a very small decrease in numbers of very blue stars with increasing latitude. In this connection, it might be pointed out that, whereas our Table II is, we hope, at least 80% complete, the total number of stars (Table IV) with color equivalent to our $U-V = 0.0$ or -0.1 is undoubtedly very much larger than our total of 4248; preliminary star counts suggest a number well over 20,000.

By and large, however, the distribution of all these blue stars as well as of the very blue stars in the region south of galactic latitude -50° does not show any departure from uniformity which can be definitely indicated from the present material.

In connection with the distribution of luminosities and distances, we can point out the following:

a) All of the groups indicated by Iriarte⁽⁸⁾ in the color-color diagram seem to be present among our stars. We are faced with the dilemma, however, as to whether such a diagram does or does not represent a relationship with luminosity. If the former is true, a large range of luminosity—from faint white dwarfs to supergiants—is present and hence it follows that many of our stars should lie at very great distances. If the latter is correct, we shall have to try and find luminosity indicators as best we can from other means.

b) Foremost among these are the proper motions Luyten has determined for more than 300 faint blue stars in high latitude with magnitudes down to 17. The number of classical white dwarfs—i. e. white or blue stars with absolute magnitudes fainter than +8—among them is small, not more than 12 or 15. Some of the stars appear to have motions indicating luminosities around +5 or +6, but for the majority the motions are so small that only a very crude indication of a luminosity from $M = +0.0$ to +3 can be given. It should be borne in mind, however, that luminosities all the way from main sequence B stars down to classical white dwarfs cannot be excluded. We should be especially careful in drawing conclusions from the proper motion material for these stars since, firstly, the mere fact that these stars are now in the galactic Corona may well mean that they have larger galacto-centric velocities than other stars with similar luminosities and spectra and, secondly, that among the fainter stars, i. e. those with say $m > 14$, only the classical white dwarfs can now be definitely identified and a separation into other luminosity groups is not possible.

c) That stars of very high luminosity exist at great distances from the Galactic Plane is indicated, e. g. by Abt's work⁽⁹⁾. (To these stars we may add several objects in our lists, of which BD $-11^{\circ}6076$ might be a good representative. Fig. 6).

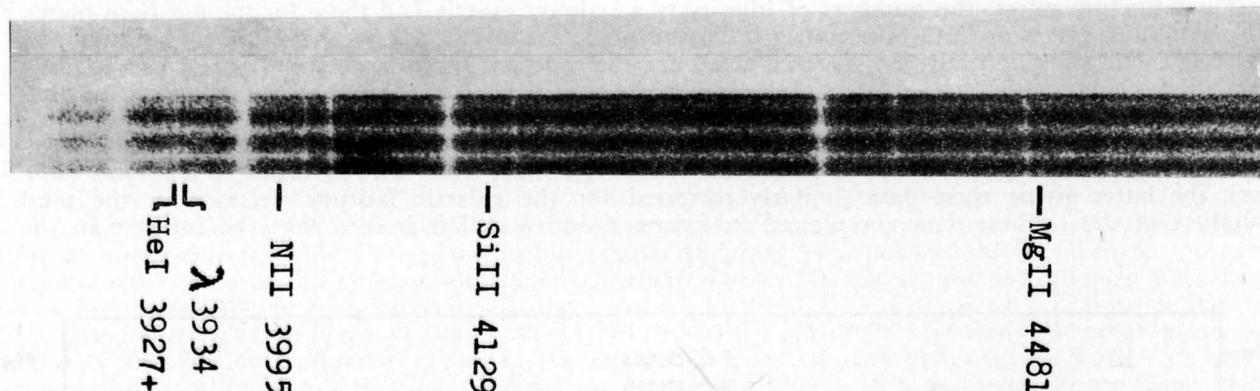

Fig. No. 6.—Spectrogram of BD $-11^{\circ}6076$, PHL 525, kindly obtained for us by Braulio Iriarte using the spectrograph attached to the 40" telescope of the Naval Observatory in Flagstaff. All the spectroscopic features that characterize a normal B3III star are present. It is interesting to note that a faint absorption line appears at $\lambda 3934$. It will be of great interest to investigate if it is an interstellar calcium line.

d) Many of our very blue variables appear to be of the SS Cygni or Z Camelopardalis types with absolute magnitudes expected to be around +5 to +8 (at minimum) tying in with the beginning of the white dwarf sequence, but some of them (PHL 563, our var. No. 5) are invisible on the Palomar Survey charts at minimum, hence are probably fainter than $m = 21$ thus indicating a modulus $m - M = +13$ or more, or distances of 4000 parsecs. One variable at least appears to possess, according to Haro and Chavira's observations, the same light variation characteristics as the R Cor Bor type (PHL 538), although it is very blue in color. If it has a correspondingly high luminosity ($M < -2.5$) its distance will be of the order of 16000 parsecs.

e) Finally we have five extremely red stars. Even if two of these may turn out to be late M giants, the other 3 appear to be definitely N stars. The faintest of these is 18.5 pg 13.8 pv; if $M_v \approx -3$ again a distance of more than 20000 parsecs is indicated.

We have seen no definite evidence that at our magnitude limit of nearly $m = 19$ we have reached the end and it seems more than likely that blue stars will be found in large numbers still several magnitudes fainter. In fact, Zwicky has indicated that they continue at least as far as $m = 23$. The conclusion seems indicated, therefore, that the extent of the Galactic Corona must be measured in terms of the order of fifty thousand parsecs and that it may well reach as far as or beyond the Magellanic Clouds.

In conclusion, we should like to express our gratitude to the Director and staff of the Mount Wilson and Palomar Observatories for allowing us guest investigator privileges, and especially to Mr. Charles Kearns who so efficiently ran the telescope for us on all our observing nights. Our thanks are also given to Mr. Manuel Peimbert and to the Computing Center of the University of Mexico for the valuable help and facilities in using the IBM machine. One of us (W. J. L.) is deeply indebted to the Hill Family Foundation for a grant which made his participation in many phases of this work possible.
