### RESUMEN

Presentamos el primer Catálogo de LINERs (de las siglas en inglés “Low Ionization Emission Nuclear Regions”), o galaxias con espectro nuclear de líneas en emisión de baja ionización. Aquí adoptaremos el nombre mas simple: Liners. El catálogo ”MCL” (por las siglas en inglés: Multifrequency Catalog of Liners) contiene 476 objetos y contiene información de la emisión en banda ancha y monocromática desde radio hasta rayos X, colores y otros datos recopilados de la literatura y de bancos de datos, como se indica en las referencias. La mayoría de las galaxias pueden considerarse Liners “puros” con base en la clasificación de Veilleux & Osterbrock (1987), como lo sugirieron Ho, Filippenko, & Sargent (1997). Sin embargo, se incluye también un número considerable de objetos de transición Liner–H II. Una de las interrogantes no resueltas, es si los Liners deben considerarse como una clase de galaxias (como por ejemplo las galaxias Seyfert), o por el contrario, representan un grupo heterogéneo. Pensamos que el estudio de los Liners como grupo, es sumamente interesante precisamente porque representan la transición entre actividad nuclear no térmica y de brote estelar, e incluso, probablemente, la transición entre galaxias “activas” y “no activas”. Este catálogo podrá usarse como base para estudios estadísticos; aquí presentamos un análisis preliminar de las propiedades estadísticas de los Liners en el rango de radio a rayos X.

### ABSTRACT

We present the first Catalog of Low Ionization Emission Line Galaxies (LINERs or Liners, which is the simplest name, and which we shall adopt in what follows). The Catalog “MCL” (Multifrequency Catalog of Liners), contains 476 entries and contains both broad-band and monochromatic emission data (ranging from radio to X-ray frequencies) of colors, and other data compiled from the literature and various data bases, as indicated in the references. Most of the galaxies can be considered “pure” Liners on the basis of the Veilleux & Osterbrock (1987) classification as suggested by Ho, Filippenko, & Sargent (1997). However, a considerable number of transition (Liners–H II or Liners–Starburst) objects are also included. One of the open questions, is whether Liners should be considered as a class of galaxies (like Seyfert galaxies for instance) or rather, as an heterogeneous group of objects. We believe the study of Liners as a group is very interesting, precisely because they very likely represent a transition between non-thermal and starburst activity, and probably also between “active” and “non- active” galaxies. This catalog may be used as a basis for statistical research. A preliminary discussion of the main statistical properties of Liners, in the range from radio to X-ray frequencies, is given here.

*Key words:* CATALOGS — GALAXIES: ACTIVE — GALAXIES: FUNDAMENTAL PARAMETERS — GALAXIES: NUCLEI — GALAXIES: STARBURST

### 1. INTRODUCTION

Almost two decades ago, Heckman (1980) found quite a large amount of Active Galactic Nuclei

(AGN) with spectroscopic properties which depart from those of either “normal” H II regions or AGN. Their principal signature was the enhancement of the low ionization lines and, therefore, the name proposed for these new objects was: “Low Ionization Nuclear Emission Regions” (LINER galaxies or Liners). These nuclei were described as systems with optical spectra dominated by lines arising from low ionization states, with moderate emission line luminosity (comparable to Giant H II Regions), and with line widths approaching those of the Narrow Line Regions (NLR) of Seyfert galaxies. In some of them, a compact nuclear radiosource was also detected. In that early work, Heckman noticed that a sequence between Liners and AGN could be drawn in which Liners occupy the low luminosity end. However, whereas AGN were broadly recognized as regions ionized by a power-law continuum (i.e., where lines result from soft X-ray ionization by the AGN, Halpern & Steiner 1983), Liners were best explained in the context of shock ionization (Fosbury et al. 1978; Dopita et al. 1996), and photoionization by post-AGB stars in the case of weak Liners in Ellipticals (Binette et al. 1994). Another problem in relating Liners to other AGN was the overabundance of Liner characteristics in early type spiral nuclei (Keel 1983a,b).

The puzzling physical nature of these objects has been pointed out by many authors. Among them, the results by Filippenko & Halpern (1984) on the Liner galaxy NGC 7213 are particularly interesting. These authors noticed that broad permitted lines were also present in the optical spectrum, which suggested the possibility that at least in some Liners the source of ionization could be a power-law continuum. On the other hand, in the work by Filippenko & Terlevich (1992) on weak O I Liners, they invoked stellar photoionization as the origin of the emission, stressing the complicated nature of Liners and opening the discussion of whether their nature has any physical meaning in terms of class of galaxies (such as Seyfert galaxies). More recent surveys at optical frequencies by Ho et al. (1997) have not solved these controversial issues. Their extensive survey of Emission Line Nuclei lead them to similar results as those in the original work by Heckman (1980). Around 20% of the nuclei of Spirals have Liner characteristic, many with broad Balmer emission lines (the so called Liner 1 using the analogy with Seyferts). The most important new result of these surveys is that Liners constitute not a class, but rather a variety of objects ranging from Liners with properties similar to Seyfert galaxies, to (“transition”) Liners with properties more similar to H II regions.

Normally, we would expect that information coming from all spectral ranges could help to disentangle and perhaps taxonomize the Liner family. But new data at different wavelengths have provoked even more discussion. The study at UV frequencies by

Maoz et al. (1998), has shown that the UV spectrum is more consistent with Starburst than with a non-thermal nature. Moreover, the lack of detection of UV sources in most of the Liners searched for by Barth et al. (1998) cast further doubt about the AGN nature of most Liners. However, different possibilities have been explored to reconcile these results with the view of Liners as quiescent AGN (see *The Physics of LINERS in View of Recent Observations*, 1996). Eracleous, Livio, & Binette (1995) have developed a very suggestive hypothesis to explain the lack of a compact UV source as a consequence of a duty cycle variability in the UV source, which is only switched on 20% of the time. Other more conservative explanation developed by Binette, Wilson, & Storchi-Bergmann (1996), has been to understand the Liner optical spectrum as a result of soft X-ray ionization from an AGN. In both cases, the UV spectrum cannot be fully explained.

We want to emphasize that most of the work on Liners has been concentrated in optical selected samples, and the results from FIR selected samples have been overlooked. The work by Kim et al. (1995) and Veilleux et al. (1995) on Luminous FIR galaxies and more recently by Kim, Veilleux, & Sanders (1998) and Kim & Sanders (1998), allows us to draw some important conclusions from both set of data. In particular, the reported evidence that the IR source of energy in Liner-like spectra (38% of the ULIGs) is of stellar origin rather than AGNs.

The above considerations motivated us to compile a multifrequency catalog of Liners selected from different sources in the literature. The main purpose of this catalog is to construct a large sample of Liners, as unbiased as possible, and to provide a basis for multifrequency statistical analysis. In the next section, it will be shown that this catalog does not unduly favor optical selected samples as it includes all the objects classified as Liners in the current literature.

## 2. THE CATALOG

The Multifrequency Catalog of liners (MCL), includes all objects from the various Liner samples known at the time of writing (1998), plus various objects compiled from the literature. It contains objects extracted from the main AGN catalogs: Lipovetsky, Netvestny, & Neizvestnaya (1987) (LNN), Veron & Veron-Cetty, 6th & 7th editions, (VCV y VCV7), Huchra (1995) (HUC), as well as NASA extragalactic data base (NED), and lists that have appeared in various recent papers such as: Ho et al. (Ho93, Ho97), Kim et al. (K95), Veilleux et al. (VK95), and Wu et al. (Wu98). The MCL is presented in Tables 1 through 6, and was constructed following the style of the Catalog of the Second Byurakan Survey Seyfert Galaxies by LNN. We describe next the content of each table.

Table 1 contains the list of Liners including: IAU name (column 1); alternative name (2); 1950 right ascension and declination (3 and 4); properties of host galaxy such as: redshift (5);  $B$  magnitude (whenever more than one determination was found, we chose the one for the large major axis) in 6;  $\text{Ext}(B)$  in 7; Hubble type (8); references to: Liner identification (9); redshift determination (10); and finaly references to  $B$  &  $\text{Ext}(B)$  in column 11. Tables 2 through 6, contain data at various frequencies and bands from radio to X-rays, and are described below.

Table 2 contains *IRAS* and radio data. In all tables ,the IAU name is in column (1); data are ordered as follows: *IRAS* fluxes in Jys for 12, 25, 60, and 100  $\mu\text{m}$ , respectively, are in cols. (2) through (5); FIR flux in  $\text{erg s}^{-1} \text{cm}^{-2}$  in (6); fluxes at 6 cm and 11 cm in Jys are in (7) and (8); fluxes at 21 cm (H I) in  $\text{erg s}^{-1} \text{cm}^{-2}$  in (9), and references to radio data are in (10). *IRAS* data comes from the *IRAS* Point Source Catalog and were taken from Kim et al. (1995), Ho et al. (1997), and NED.

Table 3 includes photometric properties of the underlying galaxy ordered as follows: dereddened  $V$  magnitude (2); dereddened optical colors ( $U - B$ ), ( $B - V$ ), and ( $V - R$ ) in cols.(3) through (5); references to optical magnitudes and colors are in (6); infrared magnitudes and colors  $J$ ,( $J - H$ ), ( $H - K$ ), and  $L$  are in (7) through (10). All references to IR data are from NED and in a few cases from Duc, Mirabel, & Maza (1997).

Table 4 contains optical spectroscopic data ordered as follows, dereddened line ratios:  $[\text{O III}] 5007/\text{H}\beta$ ,  $[\text{O I}] 6003/\text{H}\alpha$ ,  $[\text{N II}] 6583/\text{H}\alpha$ , and  $[\text{S II}] 6716+6731/\text{H}\alpha$  in cols. (2) through (5), and references (6). In (1) the following marks have been used:  $B$  for Liners with broad  $\text{H}\alpha$  emission (Ho et al. 1997);  $\text{H II}$  and  $\text{Sy}$  for galaxies that we found to be probably misclassified on the basis of the diagnostic diagrams shown in Figure 5 (this objects do not lie within the Liner region in all three diagrams simultaneously), and that are probably Starburst ( $\text{H II}$ ) or Seyfert 2 galaxies, respectively or both. The listed ratios were dereddened using Miller & Mathews (1972) parameterization for the dereddening curve given by Whitford (1958).

Table 5 contains IR spectroscopic data ordered as follows:  $[\text{Fe II}] 1.2567 \mu\text{m}$  (2);  $\text{Pa}\beta 1.2818 \mu\text{m}$  (3);  $\text{Pa}\alpha 1.875 \mu\text{m}$  (4);  $\text{Br}\delta 1.945 \mu\text{m}$  (5);  $\text{Br}\gamma 2.1655 \mu\text{m}$  (6);  $\text{H}_2 1.835 \mu\text{m}$  (7);  $\text{H}_2 + [\text{Si VI}] 1.958$  and  $1.962 \mu\text{m}$  (8);  $\text{H}_2 2.033$  and  $2.1218 \mu\text{m}$  in (9) and (10) respectively, and references in (11).

Table 6 contains UV and X-ray data in the following order: short and long wavelength UV fluxes (2) and (3), from the SW (1150–2000  $\text{\AA}$ ) and LW (1850–3300  $\text{\AA}$ ) cameras on board of *IUE*. Data were obtained following the access guide to ULDA (Ultra-violet Low-Dispersion Archive) No. 4, and also from NED. The entries are in units of  $10^{14} \text{ ergs cm}^{-2} \text{s}^{-1}$

$\text{\AA}^{-1}$ . X-ray fluxes are in  $10^{-13} \text{ ergs cm}^{-2} \text{s}^{-1}$  (4) with references in (5).

### 3. PRELIMINARY COMMENTS

We present some histograms and plots, which give us a first insight into the global properties of the compiled Liner sample. A detailed statistical analysis of these properties will be presented in a forthcoming paper.

In Figure 1, the  $z$  distribution is shown in which one can see that most Liners cluster around  $z = 0.006$ . The most distant confirmed Liner is at  $z = 0.39$ , and only 2 sources have  $z > 0.2$ . It is expected that IR selected Liners will increase the population at higher redshifts (i.e., Wu et al. 1998, see also the redshift distribution of the 1 Jy sample, reported by Kim & Sanders 1998). The  $M_B$  and Hubble type histograms are shown in Figures 2 and 3. It has to be noticed that the host galaxies of Liners (“pures” + “transitions”) are mostly normal spirals with a median  $M_B$  value of  $-20.7$ . Ho (1996), found a median  $M_B = -20.2$  for “pure” Liners. Liner type spectra do not appear very often in dwarf systems. The morphological distribution point out that Liners are preferentially in early type galaxies. The later Hubble types hosting Liner nuclei are mostly related to perturbed systems as judged from the Digitized Sky Survey (DSS).

Two color (optical and near IR) diagrams are shown in Figure 4, upon which the locus of normal galaxies has been overlaid. While the optical colors do not show strong departures from those of normal galaxies, the near-IR show a strong scatter of  $H - K$  colors, larger than 0.4. From the galaxies producing the large scatter that we were able to identify (19), 8 come from the ULIRG class (Duc, Mirabel, & Maza 1997), 2 are strong radio galaxies, in four of them an apparent distortion in the morphology is visible in the DSS. Therefore, the large spread in Figure 4b can be attributed to peculiar colors produced by a merging process.

Diagnostic Diagrams (following Veilleux & Osterbrock 1987) to separate missclassified Liners are presented in Figure 5. Squares denote the values for line ratios of Liners. We also show the regions (loci) corresponding to the ratios of nuclear spectra of Seyfert 2 galaxies or to  $\text{H II}$  and blue compact galaxies (and/or spectra of giant  $\text{H II}$  regions in galaxies). We can see that several objects do not lie within the Liner region in all three diagrams simultaneously, but this should not be surprising if we take into account that we have included all the so called “transition” objects (circles) from Ho et al. 1997. Still, there are objects which lie out of the liners loci in all three diagrams, and thus, on the basis of the ratios  $[\text{O II}] \lambda 3727 / [\text{O III}] \lambda 5007$ ,  $[\text{O I}] \lambda 6300 / [\text{O III}] \lambda 5007$ , and  $[\text{N II}] \lambda 6583 / \text{H}\alpha$ , they should be classified rather as Seyfert 2 galaxies (16 objects) and  $\text{H II}$  galaxies (6 objects).

Particular classification preferences expressed by the respective authors of the cited data:

<sup>a</sup> Transition objects that are Liner/HII-nucleus systems; Ho et al. 1993; Ho et al. 1997.<sup>b</sup> Mixture type with properties of both Liner and HII galaxy; Wu et al. 1998.<sup>c</sup> L/H emission class; Keel et al. 1985.<sup>d</sup> Ambiguous objects between HII galaxies and Liners; Veilleux, Sanders & Kim 1997.<sup>e</sup> Two criteria favor Liner and one to Starburst; Duc, Mirabel & Maza 1997.

<sup>a</sup> SW camera at 1150–2000 Å.<sup>b</sup> LW camera at 1850–3300 Å.<sup>c</sup> In units of  $10^{-14}$  ergs cm $^{-2}$  s $^{-1}$  Å $^{-1}$ .<sup>d</sup> In units of  $10^{-13}$  ergs s $^{-1}$  cm $^{-2}$ .<sup>e</sup> *ROSAT* (0.1–2.4 keV); *Einstein* (0.2–4.0 keV).Fig. 2.  $M_B$  magnitude of underlying galaxy distribution.

Fig. 3. Morphologic (Hubble) type distribution of underlying galaxies. The shaded zone covers those galaxies which do not show any peculiarities in their morphology.

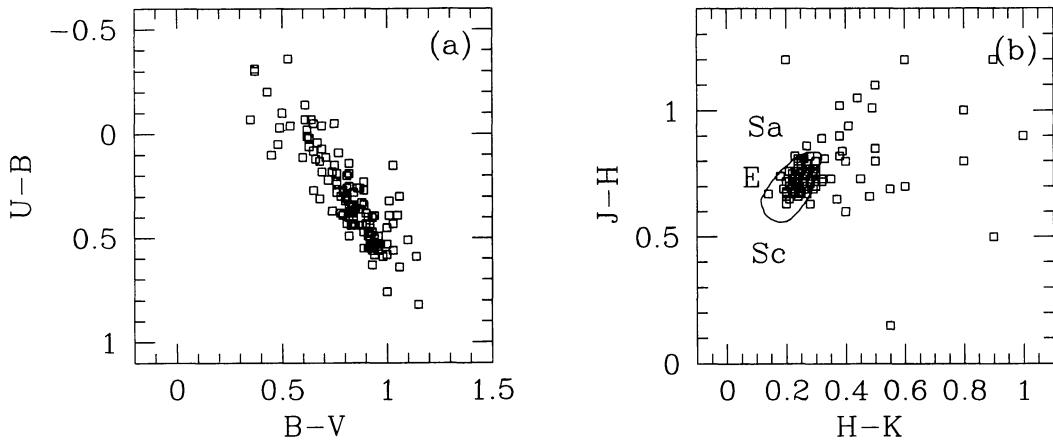

Fig. 4. Optical (a) color-color diagrams and (b) near IR color-color diagrams of underlying galaxies. In Figure 4b, the locus of “normal” Sa, Sc, and E (Hunt et al. 1997) galaxies is delineated.

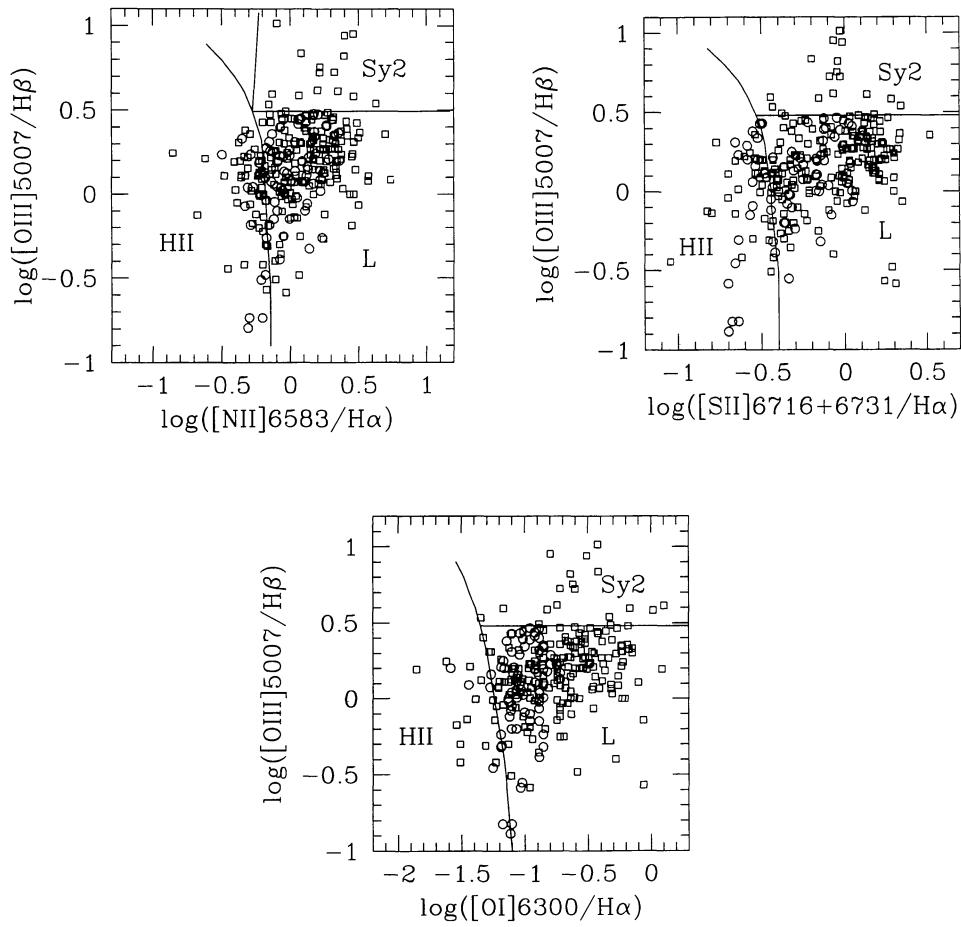

Fig. 5. Diagnostic Diagrams (following Veilleux & Osterbrock 1987). Squares denote the values for line ratios of Liners, and “transition” objects (circles) from Ho, Filippenko, & Sargent 1997. We also show the regions (loci) corresponding to the ratios of nuclear spectra of Seyfert 2 galaxies and for H II or blue compact galaxies (and/or spectra of giant H II regions in galaxies).

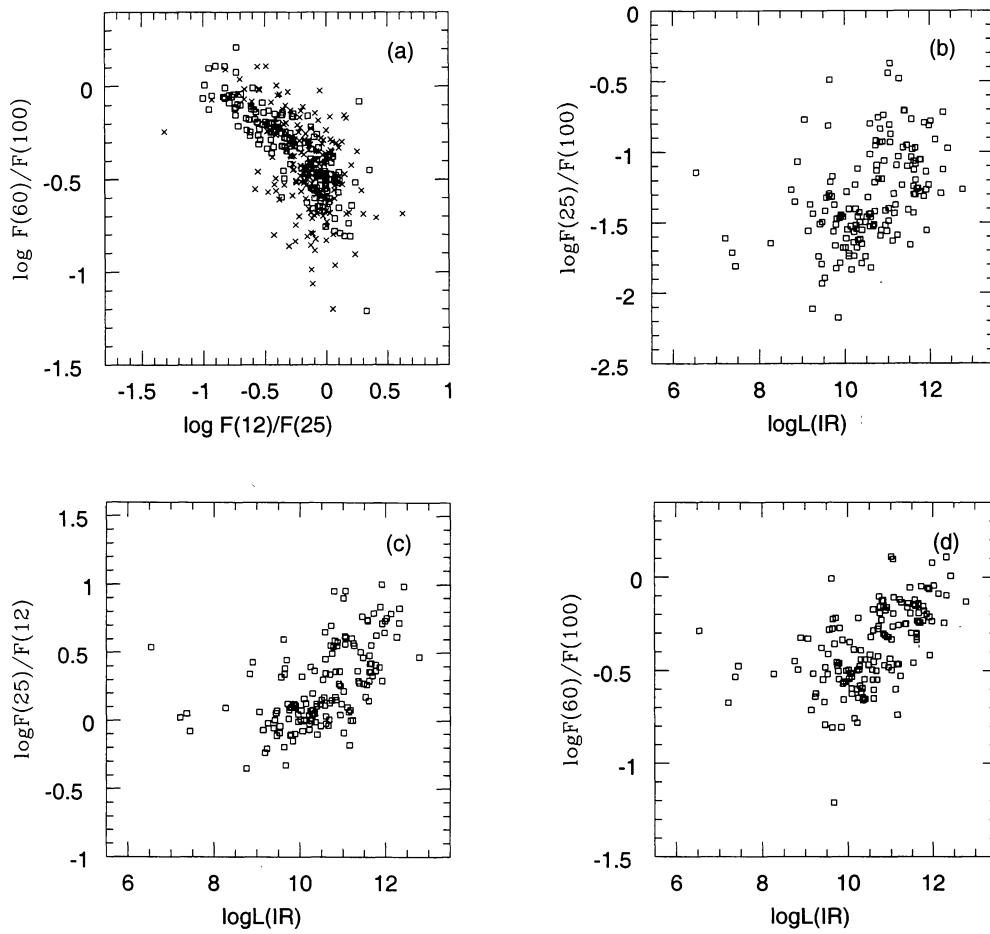

Fig. 6. The *IRAS* data. In Figure 6a, the ratio  $F(60)/F(100)$  versus  $F(12)/F(25)$ , is shown for all objects in the catalog. Squares are for sources detected in all *IRAS* bands, and crosses for those which are not detected (or have a limit value) in at least one band. In Figures 6b, 6c, and 6d, we use only objects detected in all *IRAS* bands to plot  $F(25)/F(100)$  versus  $L(\text{FIR})$ ,  $F(25)/F(12)$  versus  $L(\text{FIR})$ , and  $F(60)/F(100)$  versus  $L(\text{FIR})$ .

Figure 6 shows *IRAS* data. In Fig. 6a the ratio  $F(60)/F(100)$  versus  $F(12)/F(25)$  is shown for all objects in the catalog. Squares are for sources detected in all *IRAS* bands, and crosses for those which are not detected (or have a limit value) in at least one band. In Fig. 6b, Fig. 6c, and Fig. 6d we use only objects detected in all *IRAS* bands (no upper limits have been included) to plot  $F(25)/F(100)$  versus  $L(\text{FIR})$ ,  $F(25)/F(12)$  versus  $L(\text{FIR})$ , and  $F(60)/F(100)$  versus  $L(\text{FIR})$ . The large scatter in all the diagrams seems to point out the heterogeneous character of the sample we are dealing with. Although all the colors show the same trends, dust temperatures become hottest as the IR luminosity increase.

Finally, in Figure 7 we present the histograms of the luminosities in all the bands from radio to X-ray

frequencies. The data seem to suggest that both in radio and X-ray frequencies, the range in luminosity is quite large and cannot be considered as a well defined property of the Liner population.  $B$  and FIR luminosities, however, show a lower range in luminosities which is suggestive of a better defined global property for the reported galaxies.

We are grateful to our referee for his comments that helped to improve the final version of this paper. We wish to thank Luc Binette for comments and suggestions. This work was supported by grant IN109896 from PAPIIT, UNAM (México), and DG-CYT grant PB93-0139 (Spain). We like also to acknowledge Junta de Andalucía and the Instituto de

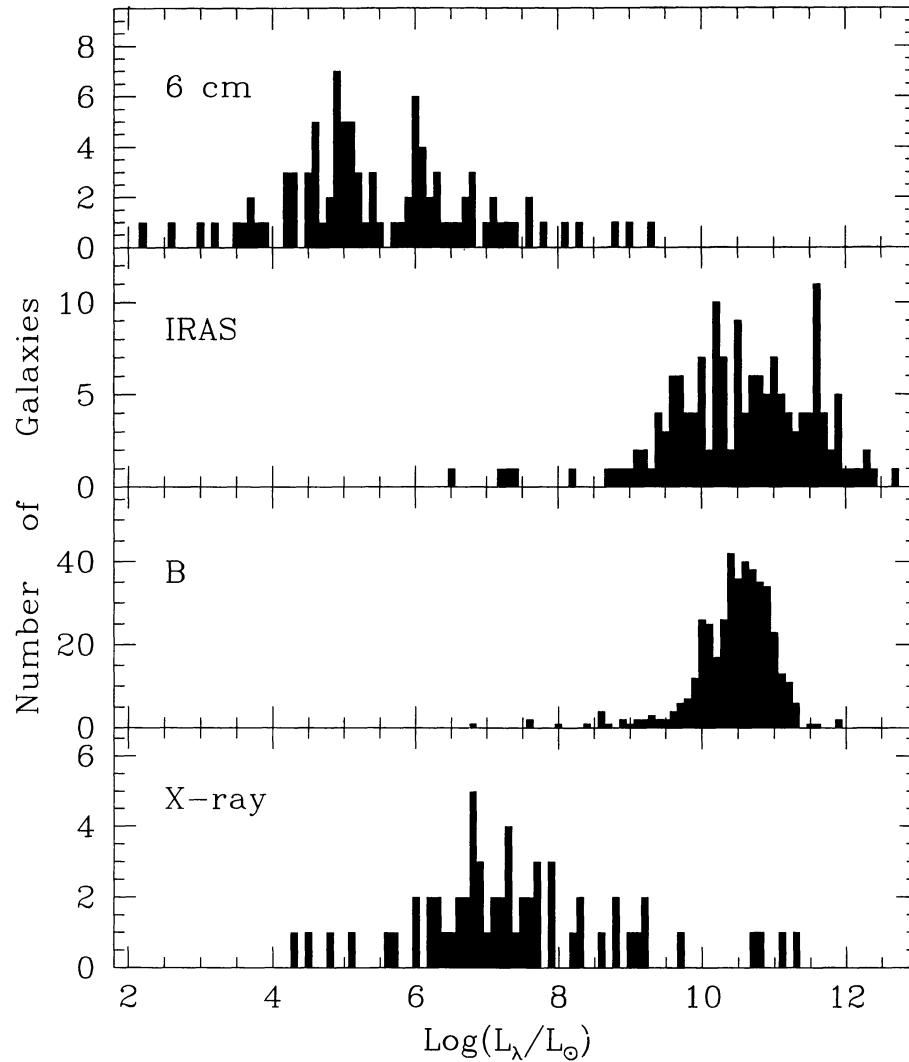

Fig. 7. The luminosity distribution in four bands: 6 cm, FIR (using sources detected in all four *IRAS* bands), *B*, and X-rays. The objects used for this figure are the same (i.e., those which have measures in all four bands from radio to X-rays).

Astrofísica de Andalucía (Spain) for partial financial support. R.C. acknowledges partial financial support from CONACYT and DGAPA (UNAM), México that allowed him to spend his postdoctoral year at the Instituto de Astrofísica de Andalucía. R.O. acknowledges support from DGEP, UNAM, through an undergraduate scholarship.

This research has made use of the NASA/IPAC extragalactic database (NED) which is operated by the Jet Propulsion Laboratory, Caltech, under contract with the National Aeronautics and Space Administration.
