

OPTICAL COORDINATES OF SOUTHERN PLANETARY NEBULAE

S. Kimeswenger

Institut für Astrophysik, Universität Innsbruck, Austria

Received 2000 December 29; accepted 2001 April 4

RESUMEN

Se aporta un conjunto homogéneo de nuevas medidas de casi todos (995 de 1007) los objetos del catálogo de Strasbourg-ESO de nebulosas planetarias galácticas, o del primer suplemento de este catálogo, en el área cubierta por el DENIS survey ($\delta < +2^\circ$). Se presentan también 24 nuevas y 27 falsas identificaciones con fuentes en el catálogo IRAS PSC y una cierta confusión en la literatura se enumera también.

ABSTRACT

A homogeneous set of new measurements of nearly all (995 out of 1007) objects from the Strasbourg-ESO Catalogue of Galactic Planetary Nebulae or in the first supplement of this catalogue in the area covered by the DENIS survey ($\delta < +2^\circ$) is given here. A list of 24 new and 27 wrong crossidentifications with sources in the IRAS PSC catalogue and some confusion in the literature is listed as well.

Key Words: PLANETARY NEBULAE: GENERAL

1. INTRODUCTION

In the course of the preparation of a catalogue of near infrared (NIR) sources of the DENIS survey (Epchtein et al. 1994, 1997) and during the measurements of planetary nebulae (Kimeswenger et al. 1998a), we found that the optical coordinates of a significant portion of the known galactic planetary nebulae (PNe) were inaccurate. These inaccuracies impair the use of automated cross-identifications for, e.g., colour-colour diagrams (Kimeswenger 1997). Also a wealth of problems arise in electronic data bases (Kimeswenger et al. 1998b). The coordinates of the objects in the large PNe-catalogues (e.g., Perek & Kohoutek 1967 = CGPN; Acker et al. 1992a = SECGPN; Acker, Marcout, & Ochsenbein 1996) were taken mostly from the original literature. Even the coordinates in the IAC Morphological Catalog of Northern Galactic PNe (Manchado et al. 1996) are not derived from the images, but just copied from the SECGPN. Thus, this catalogue cannot be considered as a northern counterpart to the compilation presented here. More accurate optical coordinates of a small set of nebulae were redetermined later (Milne 1973, 1976; Blackwell & Purton 1981). The accuracy of the recently detected objects is in most cases rather good. However, older coordinates are often given to $\pm 0.1'$ or worse. Also,

a considerable number of central stars (CSPN) of extended nebulae have been identified in the meanwhile. These nebula have got a better defined “center”. A low accuracy is insufficient for satellite observations or for those with the new generation of very large telescopes. Merely the identification on the crowded $12' \times 12'$ fields coming from the DENIS survey was often quite difficult (Epchtein et al. 1994). We measured all coordinates by means of the Digital Sky Survey and some supplementary material, like CCD digitisation from the Schmidt plate copies for faint nebulae or *I* band images obtained by the DENIS survey. Although for a small number of nebulae there exist more accurate radio coordinates, we measured those nebulae too and thus obtained a highly homogeneous data set of optical coordinates.

2. NOMENCLATURE

The name (identifier) of the nebula is usually formed using the galactic coordinates (truncated to one tenth of a degree)

PN *GLLL.l±BB.b*

as it was proposed for PNe by Acker et al. (1992a). A change of coordinates would imply a change of the name identifiers. According to the recommendations of the IAU (Lorette & Spite 1986; Dickel,

Loretet, & deBoer 1987), and in order to avoid severe confusion, no changes of the identifier should be applied later. This procedure is also used in data bases like, e.g., SIMBAD. The used identifiers are just starting to get ambiguous. The current lists (true PNe only) have not had a real problem up to now (except for one case where a letter had to be added). This was also done in other data bases, e.g., the IRAS data base. But here the situation differs: there are no new entries being added to the IRAS data base anymore. However, the currently running surveys for PNe and emission line objects in general (e.g., Parker, Phillipps, & Morgan 1999; Beaulieu, Dopita, & Freeman 1999; van de Steene & Jacoby 1999; Beaulieu 2000) will add a few hundred sources in the bulge region within the next few years. Thus, and since the accuracy of coordinates is now significantly better than 0.01 degrees ($\equiv 36''$), we suggest the use of

GPN *GLLL.ll±BB.bb*

in the future. The descriptor GPN stands for galactic planetary nebula. The remaining string is formed as described in the dictionary of nomenclature cited above. This also fulfills the recommendations of the IAU Dictionary of Nomenclature, where a list identifier should contain at least 3 characters (the ‘G’ after the blank does not count as it is part of the coordinate) and the coordinate should be chosen not to be unambiguous, but to the limit given by the expected coordinate accuracy (worst case).

3. THE DATA

A $5' \times 5'$ field at the nominal position as given in the SECGPN of each source was loaded from the Digital Sky Survey (DSS). These maps were compared, as far as possible, with the finding charts of the original discoveries and with those given in the SECGPN and the CGPN. The coordinates of these plates were calibrated by means of the Guide Star Catalogue (GSC). This yields coordinates better than the pixel resolution (relative to the GSC reference frame). In case of compact nebulae and extended nebulae, where the CSPN could be identified on the DSS scans (the vast majority of the objects), a Gaussian fit was used to derive the position. If an object was too faint on the DSS scans, a CCD scan of the Schmidt plate copy (by means of a microscope system) was obtained. In a few cases the images of Schwarz, Corradi, & Melnick (1992) were taken. In one case (A 58) the image in Pollacco et al. (1992) and in Kimeswenger, Koller, & Schmeja (2000) was used; in another case (NGC 5189) that in Kimeswenger et al. (1998a). In the case of about 15

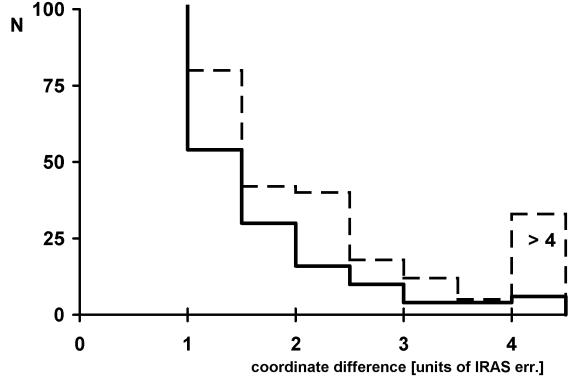

Fig. 1. Frequency histogram of the positional difference between the determination in this work and the positions given in the SECGPN and in Acker et al. (1996).

recently discovered nebulae (Jacoby & van de Steene —listed in Acker et al. 1996) for which only NIR finding charts were available, the *I* band images of the DENIS survey were used. The positions of these auxiliary frames were calibrated by use of the DSS scans. This method gives an overall accuracy $< 1''$, relative to the GSC stars. In the case of a small number of very extended irregular nebulae without a known CSPN, the geometric centre (of the smallest circle embedding the object) was chosen. The coordinates of all objects are given in Table 1. Remarks corresponding to misidentifications on the finding charts (FC) in Acker et al. (1992a) or Acker et al. (1996) are given as supplementary information. For 12 nebulae no identification was possible (listed in Table 2).

For a set of objects (88), multiple records and misclassifications from the literature, mostly “galaxies” from sky survey plate searches are listed in the SIMBAD data base (current status). Those are also listed in Table 1. In some not so obvious cases, they are described in detail in § 5. Figure 1 gives a frequency histogram of coordinate offsets between those listed in the catalogues and those measured here. As can be seen from the diagram, the new determination of coordinates led to a marked improvement for a significant fraction of PNe.

4. CROSSIDENTIFICATIONS

4.1. IRAS

The existing crossidentification with IRAS sources were checked by means of the coordinates and the error ellipse of the IRAS PSC (which corresponds to a 2σ correlation). In the case of extended sources the outermost region of a nebula was used

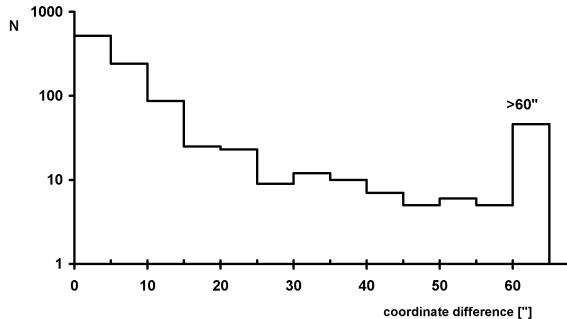

Fig. 2. Frequency histogram of the positional differences between the determination in this work and the positions of the identified IRAS PSC sources (solid line) and those of SECOPN positions to the same IRAS PSC sources after removing the rejected sources (dashed line).

for the boundary condition. The coordinate information and the size of the IRAS error ellipse were used mainly for the decision. Each rejection was then investigated individually on the basis of IR colours, size, and morphology of the nebula. In a few cases the coordinates are within the errors, but another bright object (usually a star) is more likely to be the correct identification. A total of 27 (4.5 %) objects listed as IRAS PSC counterparts in Acker et al. (1992a, 1996) were rejected as proper optical counterparts to the IRAS source. Sources without an identification with an IR source were checked with the IRAS-PSC on the basis of coordinates and IR colours. This results in 24 new identifications. The identifications assumed to be correct are listed in Table 1 and Table 2. The rejected objects are given in Table 3. In Figure 2 the frequency histogram of the differences of the source position between the IRAS PSC source and the coordinates measured here and that of the object in the SECOPN to the IRAS source is shown.

5. INDIVIDUAL OBJECTS

Some individual objects erroneously classified or identified as PNe or being doubtful PNe are separately discussed as follows:

GPN G254.67+00.21 = PN G254.6+00.2 =

Ns 238. This object has neither the morphology of a PN, nor are the IRAS colours and the total FIR flux suitable for a PN. Thus it was included in a sample of star forming regions by Chan, Henning, & Schreyer (1996). Also the NIR photometry with a wide beam (Liseau et al. 1992) is more likely that of a star-forming region (Kimeswenger & Weinberger 2001).

Rousseau & Perie (1996) list four stars in that region (VdBH 13aA, 13 aB, 13b, and 13c) as “embedded in a reflection nebula”. The survey of OH emission towards post-AGB stars (teLintel Heckert & Chapman 1996) led to no detection, while the region appears rather bright in CO (Wouterloot & Brand 1989). Goebel, Cheeseman, & Gerbault (1995) select this source as an IRAS LRS possible carbon star having some unusual features around $11 \mu\text{m}$. The IRAS source is not well associated with the nebula and the brightest star, which is classified as a K giant, is somewhat displaced towards west. Inspecting the images of Schwarz et al. (1992), I found that there is a lot of H α emission towards the location of the IRAS source and an indication of a bipolar structure, while [O III] emission is found only around the stars cited above, towards the edge of the system. Thus the nature of this object has to be questioned.

GPN G261.15+00.24 = PN G260.7+00.9 = Vo3 = PN G260.1+00.2. This object was identified by Volk in a spectroscopic survey of IRAS sources (priv. comm. to Acker) as a planetary nebula. The finding chart in the SECOPN is correct. Also, the crossidentification to IRAS 08355–4027 is correct. The nebula is misidentified in Acker et al. (1992a) as one given in Holmberg et al. (1978): there it is identical to BRAN 174 (Brand, Blitz, & Wouterloot 1986) and identified as an H II region around the emission line stars ESO-HA 161 and ESO-HA 162 (Pettersson & Reipurth 1994). The real PN is identical to BRAN 163 and was “rediscovered” as PN 0835-4027 by van de Steene & Pottasch (1993) and thus the identifier PN G260.1+00.2 was assigned (Acker et al. 1996).

GPN G272.40–05.96 = PN G272.4–05.9 = MeWe 1–1 = Bran 199 = ESO 165-6. Feitzinger & Galinski (1985) identify this object as an elliptical galaxy with many stars superimposed. The ESO Uppsala survey remarks: “possible neb.”. The morphology and spectroscopy (SECOPN) indicate clearly its nature as a PN.

GPN G358.01–02.73 = PN G358.3+02.6 and

GPN G358.39–02.50 = PN G358.5–02.5. Those nebulae are reversed in the SECOPN.

| 359.02+01.16 | 359.0+01.1 | JaSt 9 | |
| 359.23+01.36 | 359.2+01.3 | JaSt 8 | |

While the finding charts are correctly given as in Allen (1979), the identification was wrong (just the opposite). This leads to some confusion with the previously defined PK identifiers in the data bases.

GPN G358.88+00.05 = PN G358.8–00.0

This nebula is attached to the identifier Terz N 2022 in the SEC-GPN and in SIMBAD (Terzan & Ounnas 1988) In the data base at the same coordinates a nebula named Terz N 124 is given; the origin for this identifier might be the work of Acker et al. (1992b) were it is given as TeGo 124. There are no finding charts available. But as the coordinates are identical to arcseconds, it is assumed that this is the same source. The coordinates of the IRAS source 17395–2950 are identical too. This source is extremely cold according to the FIR.

GPN G011.39+17.98 = PN G011.4+17.9 =

PK 011+18 1 = PK 011+17 1. This object is labelled in the supplement to the SEC-GPN as DHW 2. There exist two discovery lists of Dengel, Hartl, and Weinberger (Dengel et al. 1979, 1980) The more commonly known second one has the identifiers DHW (and sometimes DeHt). Thus we use the identifier DHW 1–2 (similar to recent the recent work by Saurer et al. 1997) for this object to avoid overlap with the second

object in the second list. In SIMBAD two independent entries at the same coordinates are given.

KeWe 1 = KW 11. The nebula KeWe 1 (Kerber & Claeskens 1997) is identical to that indicated as KW 11 (Kerber & Weinberger 1995). KW 1, as used in Acker et al. (1996), has nothing to do with KW 1 = IRAS 00592+6530 = KLW 9 used in SIMBAD.

KeWe n = KW n n = 2,3,4,5. The nebulae KeWe 2, 3, 4, and 5 (Kerber et al. 1998) are identical to those indicated as KW 2, 3, 4, and 5 in SIMBAD and identical to KW 6, 8, 9, and 13 in Kerber & Weinberger (1995).

6. CONCLUSION

The considerable improvement of coordinates and elimination of misidentifications presented in this paper are important steps in refining the existing catalogues of galactic planetary nebulae. This gives a powerful tool for automated and semiautomatic crossidentification for forthcoming surveys in other wavelengths and for the observations with space-borne equipment or large telescopes of the next generation.

This project was supported by the FWF projects P8700-PHY, P10036-AST and P11675-AST. The

Digitised Sky Survey is based on photographic data obtained using the UK Schmidt Telescope. The UK Schmidt Telescope was operated by the Royal Observatory Edinburgh, with funding from the UK Science and Engineering Research Council, until 1988 June, and thereafter by the Anglo-Australian Observatory. Original plate material is copyright from the Royal Observatory Edinburgh and the Anglo-Australian Observatory. The plates were processed into the present compressed digital form with their permission. The Digitized Sky Survey was produced

at the Space Telescope Science Institute under US Government grant NAG W-2166.
