MODELING THE BUILDING BLOCKS OF WATER MASERS IN CEPHEUS A

L. Uscanga,[1] J. Cantó,[1] S. Curiel,[1] J. M. Torrelles,[2] and L. F. Rodríguez[3]

Recent VLBA observations of water maser emission from the star-forming region Cepheus A have shown that this emission actually comes from a set of coherent features or "building blocks".

These building blocks are small linear structures of water maser spots that conform a larger configuration with a well-defined linear/arcuate shape. In small angular regions, the VLBA observations (Torrelles et al. 2001) show that:

1. The water maser spots form a well-defined linear chain in the plane of sky.

2. A single spectral line with a width of 0.5 to $1\,\mathrm{km\,s^{-1}}$ in the flux density vs. velocity graph.

3. A coherent structure and a well-defined velocity gradient in the position-velocity diagrams. A conspicuous example of these results is the R5-a block containing the strongest maser spot of the entire region ($\sim 200\,\mathrm{Jy\,beam^{-1}}$, see Figure 1).

This building block is modeled as a thin disk of radius r, and thickness h, of material flowing in the direction θ with a linear velocity gradient a. The observer is in the disk plane.

The following equation was used to express the intensity from each point of the disk at a given velocity:

$$I(v,y,z) = I_0 \exp\left\{ \int \kappa_0 e^{-(v-v_\mathrm{r})^2/\Delta v^2}\, dx \right\}, \quad (1)$$

where the term in brackets is the optical depth and v_r is the radial velocity of the flow at the position (x,y). I_0, κ_0, and Δv are supposed homogeneous throughout the disk. Once the parameters are specified, we compute the flux density, $F(v)$, and the coordinates of the emission centroid at velocity v, $y_\mathrm{c}(v)$ and $z_\mathrm{c}(v)$. The results are compared with the observed maser spots of the R5-a block (Figure 2).
