TAKE A LOOK AT THE ANCIENT OBSERVATORIES IN IRAN AND PROSPECTS FOR THE FUTURE

F. Kayanikhoo\textsuperscript{1} and F. Bahrani\textsuperscript{1}

1. INTRODUCTION

Iran, from ancient years was an excelled country in construct and use of astronomical buildings. It’s obvious, that in a country with clear and beautiful starry nights people tend to discover this beautiful firmament secret. Using these astronomical buildings and instruments for calendar and discovering sky by Iranians, show their wisdom and knowledge and rich culture. Historical-astronomical buildings in Iran are includes: Shahr-e-Goor observatory, Maragheh observatory, Historical buildings Persepolis and Naghsh-e-Rustam solar observatory. We introduce two of these buildings. Iran already has a number of observatories. Some of these observatories are robotic and autonomous. One of these is observatory of University of Kashan. Also, the Iranian National Observatory is a relatively large robotic observatory that is being constructed. We will continue to introduce the properties of these observatories.

2. ANCIENT OBSERVATORIES

2.1. Shahr-e-Goor observatory

Shahr-e-Goor observatory is one of the most ancient observatories in Iran history (Fig. 1). Professor "Dietrich Huff", German Archaeologist, in excavation of Firuzabad found a circle structures which after studying; it was found that this is the most ancient observatory left from Sassanian era (Ifonso 1970).

Adobe and clay made astronomical benches which show months, are still perfectly in good condition. This have 65.5 meter diagonal and 12 marks of used sign in observational measurements and schematic benches. Probably these circular structures were in use for installation of sinusoidal device (Huff 1996).

2.2. Naghsh-e-Rustam observatory

Naghshe-e-Rustam is name of a locale that stymie’s in Fars province in south of IRAN. Solar
observatory of Naqsh-e-Rustam is located in front of the crypts and is in short distance from Mountain (Fig. 2) [Bazoband 2013]. From 1200 B.C. to 625 A.H. (1228 A.D.) this building was known as a sacred place.

Building of Naqsh-e-Rustam is Cube-shaped tower with square rule that is about 12.5 m tall and the length of each side is about 3.5 meters. In building of the tower only white and gray limestone are used, which have polished spectacularly and expertly placed close together and there was no need to stuff. On the each of the three sides, eastern, western and southern of the building, six window shape solar indexes are seen which made of gray stones. Changes in the angle between the edges of the solar indexes are equal to the changes of angle of the sunrise in various months of a year. The deep sides of solar cymbals are not perpendicular to other sides but there are slightly deviations to adjust inner corners shadow. If there were not this little deviation so there were no shades. Building of Observatory is located in certain distance of mountain how that can observe sunrise in summer solstice beside Eastern edge of the mountain and can observe sunset in autumnal equinox and vernal equinox beside the Western edge of the mountain. Northern steps of building 25 cm wide stairs. These steps are masonry in the role of the plane degrees. Their duty is calculating the time by use of altitude of sun. Angle of gradient toward ground is exactly equal to angle between the highest and lowest altitude of sun in midday, (47 degree equal to 83.5 − 36.5) or in other word is equal to degree of distance of Summer Solstice and midwinter (23.5 + 23.5) [Moradi Ghiasabadi 2001].

3. THE ROBOTIC OBSERVATORIES OF IRAN AND PROSPECTS FOR THE FUTURE

3.1. University of Kashan observatory

One of the Iran’s robotic observatories is observatory of university of Kashan. Dome of this observatory is robotic and controllable. Main telescope of this observatory can become under the control with computer and internet and as motion of the dome is depended to motion of telescope, so, this observatory can be controllable by internet.

3.2. Iranian National Observatory (INO)

Plan of designing this observatory was introduced in 1999. After researches, 3600 meter high Mount Gargash in Zagros Mountains is chosen for this observatory. The telescope with 3.42 meter diagonal mirror is first research telescope of Iran. This telescope will install on Alt-Azimuth mount and with precise computerized controllers can lead it to arbitrary points. Sets of tools of record and evaluation or detectors for different use such as photometries, recording camera, spectrometries and polarimetries will design and produce. System of tools that will use in National Observatory have to can carry a telescope with 60 ton weight with 0.01 arc seconds precise. In addition of software of controlling motion of telescope. Tower of this observatory is a cylinder with 14.5 meter diagonal and about 21 meter height (Fig. 3). This structure that is so precise and complex will make of Aluminum and some other materials and will be compiler with telescope and will rotate in both directions.
